دراسة عن الطفليات التي تصيب الخيول بمحافظة أسوان

رفعت خليفة ، محمود الهادي ، أحمد منصور

قام الباحثون بدراسة الطفليات التي تصيب عدد 184 حيواناً من الفصيلة الخيلية
(138 حصان و 44 حمار و 16 بغل) من مناطق مختلفة بمحافظة أسوان بصعيد مصر.
وقد أمكن اثناء هذه الدراسة تقييم وتقدر نسبة الأمراض بالطفليات المختلفة التي تصيب
الخيول في منطقة أسوان وهذه الطفليات هي: نوتياليكاوي 3.20% ، بابيرياكابالسي
5.6% ، هابرونياماسكي 8.4% ، باراسكاسكروम 5.8% ، سترينجولسولفارس 4.26%.
ستيرياكوينيا 9.4% ، فاشيولا جيجانتيكا 3.6% و دكتيوكولس أرغيليدي 3.8%.

كذلك أمكن الباحثون دراسة ظهور بيرقات الغيلارية لكل من ستيرياكوينيا وانكوبرز
ريتيكوينات في الدم الطرفي وقد أمكن لأول مرة معرفة أن هذه البرقات تظهر في الدم ليس
وehlera دون اختلاف كذلك أمكن دراسة ظهور بيرقات الغيلارية خلال عام كامل لمعرفة مدى
انتشارها في الفصول المختلفة وأمكن معرفة أن هذه البرقات تكون أكثر انتشارا خلال فصل
الصيف والشتاء والخريف ونقر في فصل الشتاء.

ويعتبر هذا النسج لطفليات الفصيلة الخيلية هو الأول من نوعه في منطقة أسوان.
بصعيد مصر.
A STUDY ON THE PARASITES INFECTION EQUINES IN ASSIUT GOVERNORATE
(With 4 Tables & 4 Plates)

By
R. KHALIFA; M.E.M. MONIB and A.M. MANDOUR
(Received at 20/4/1988)

SUMMARY

A survey of the parasites of 184 equines (138 donkeys, 34 horses and 12 mules) from different localities in Assiut Governorate Upper Egypt, was done within the period from October 1986 till Sept. 1987. The following rates of infection were estimated: N. equi 10.3%, Babesia caballi 6.5%, Onchocerca reticulata microfilariae 32.6%, Setaria equina microfilariae 19.6%, Habronema muscae 45.8%, Parascaris equorum 12.5%, Strongyulus vulgaris 60.4%, Setaria equina adults 22.9%, Fasciola gigantica 6.3% and Dictyocaulus arnfieldi 8.3%. The distribution of these parasites among donkeys, horses and mules was estimated and recorded. Microfilariae of Setaria equina and Onchocerca reticulata are for the first time found to be completely non-periodic, showing the same parasitaemia levels day and night. Seasonal variation of microfilarial infections is studied and was found to be more common during autumn, spring and summer than winter. The present work is the first survey of equine parasites in Assiut Upper Egypt.

INTRODUCTION

Equines play an essential role in the transportation in the field work of the farmer especially in under developed countries. However, these animals have not yet been given sufficient care, although, they are always subjected to many parasitic diseases which affect viability and lowering its laborious work.

Studies on the fauna of parasites of equines have received much attention in recent years in various countries. In BRAGUE (1959) JIRINA found 35.9% of horses infected with Setaria equina. In BULGARIA, STOIMENOV (1963) found that 26.2% of horses infected with S. equina. Also, BLACKWELL (1973) and MACRUIZ, et al. (1981) studied the clinical manifestations caused by Strongyulus worms, S. equina, Habronema sp., Dirofilaria, Peequorum and Fasciola sp., which are the cause of digestive disturbclusions, diarrhoea, anaemia, Swelling of the lower eye lid, Conjunctiva and dermatitis. On the other hand, RYLANDS (1971) and ORR (1972) recorded that Peequorum might perforate the small intestine of equines, with severe peritonitis. Also, FINAZZIL, et al. (1977), detected Habronema sp. Larvae in the C.T. of the prepuce and glans penis of equines. In Egypt, SELIM and FOUAD (1964) found microfilariae of S. equina and O. reticulata in the blood of 38.8% of horses 26.1% in donkeys and 12.5% in mules in Giza province. Also, HELMY, et al. (1967) incriminated O. reticulata as the cause of fistulous withers.
Blood Protozoa of equines have attracted many investigators in several parts of the world as BASSET and AUGERL (1931) who described the symptoms of equine piroplasmosis to be fever, weakness, jaundice and oedema of the breast, and sometimes of the limbs. In 1944, Prud'hom recorded an outbreak of equines due to B.caballi. ANGELOVSKI (1957), reported B.caballi infection which was 45% and B.equus 55% in horses. SIMPSON, et al. (1967) described B.caballi & B.equus in Florida. In the same year, Uluberg, reported Nequii infecting five cases of horses. Furthermore, FRIEDHOF and LIEBISCH (1978) described the clinical symptoms in case of B.caballi infection in the form of fever, anemia, icterus, gastroenteritis and lameness. In Egypt, MOHAMED (1979), found that 53.7% of donkeys were infected with Nequii and 3 out of 654 animals infected with B.caballi.

Therefore, the present authors were stimulated to study the prevalence of parasites infecting equines in different localities in Assiut Governorate, Upper Egypt, in an attempt to furnish a better picture of parasites of Egyptian equines in this territory.

**MATERIAL and METHODS**

Random samples from 184 equines (138 donkeys, 34 horses & 12 mules) were collected during one year from different localities in Assiut territory, (Suburbs and near the villages). These animals were admitted to the clinic of the faculty of Vet. Med. Assiut University within the period from October 1986 till September 1987.

For studying the microfilariae and the blood protozoa a thick and thin blood films were prepared from the ear veins of all the investigated animals. Films were made 3 times daily at regular intervals during day and night for three days to study the microfilarial periodicity among the microfilaraic animals. Moreover, the blood was mixed with fullyborn fluid 1ml. blood + 10ml. fluid) to facilitate the examination of blood for the microfilariae according to SELIM and FOAUD (1964). Out of the previously mentioned animals, forty eight were sacrificed and their lungs, livers and intestines were examined for adult parasites.

**RESULTS**

(1) **Protozoan parasites:**

*Nuttallia equi* and *Babesia caballi* were encountered in the red blood corpuscles of equines with a total percentage of infection 10.3% & 6.5% respectively (Table 1, & Plate 1). Fourteen out of 138 donkeys (10.2%) were found infected with *Nequii* and nine out of 138 (6.6%) also, were infected with *B.caballi* in the same host. In horses, the infection rates with *Nequii* and *B.caballi* were 11.8% respectively. Mules were noticed to be infected with the two protozoal parasites at a rate of 8.3% for each species. Mixed infection was encountered in donkeys and horses at 1.5% & 2.9% respectively.

(2) **Microfilariae:**

Microfilariae of *O.reticulata* and *S.equina* were encountered. The rates of infection were 31.2% & 18.8% in donkeys, 41.2% & 23.5% in horses and 25% & 16.7% in mules respectively.
PARASITES OF EQUINES

(Table 2 & Plate 2). A mixed infection with the two microfilariae were encountered in 13.7% in donkeys, 17.7% in horses and 16.7% in mules.

Monthly investigation of equine microfilariae in peripheral blood all over one year was done. Studies revealed a fluctuation of infection rate with microfilariae among the different species of equines. (Table 3 & Plate 3). In donkeys, the rate of parasitaemia was highest during April and May. While it was lowest during March. In horses, the highest rate was in June and September while in mules, it reached 50% during November, April and September.

Daily monitoring of the microfilariae in the peripheral blood showed no periodicity, where the microfilariae appeared at the same concentration day and night.

(3) Helminth Parasites:

Six helminth parasites were encountered (Table 4 & Plate 4). Donkeys were found to harbour all the six parasitic helminths encountered. The infection rates were recorded (S. vulgaris 56.4%, H. muscaec 46.2%, S. equi /equor 23.1%, D. annfieldi 10.2% and F. gigantica 5.1%). In horses, the most common species of helminths were S. vulgaris 71.2%, followed by H. muscaec 42.5% and S. equi 28.6%. The less common species encountered were P. equor and F. gigantica with an infection rate of 14.3% for each species (Table 4 & Plate 4). In mules, only three species of helminths were encountered; S. vulgaris 100% and H. muscaec & P. equor 50% for each species. Mixed infection was noticed in most of equines examined.

DISCUSSION

The identification of the parasites collected during the present investigations was done according to that described by YORK and MAPLESTONE (1926), MORGAN and HAWKINGS (1951) YAMAGUTI (1961) and LEVINE (1973).

In Egypt, SELIM and FOUAD (1964), HELMY, et al. (1967), FAHMY (1972), MOHAMED (1979), MORCOS (1979), and AHMED (1984) also studied the parasites among the different species of Egyptian equines. Most of them gave the prevalence of infection among equines which differs according to locality as well as other factors of climatic and environmental conditions.

From tables & Plates 1, 2, 3 & 4, it is obvious that equines were encountered with nine parasites of different species and genera. The high prevalence infection rates among equines were S. vulgaris which reached to 100% in mules, followed by horses 71.2% and finally donkeys 56.4%. The mean rates of infection in general were 60.4% among equines, the infection with H. muscaec was also considered high, the worms were found in 50% of mules, then 46.2% in donkeys, while horses harboured the low infection rate which was 24.9%. The mean rate of infection was 45.8%. On the other hand, the mean infection rates with other parasites were 22.9% S. equi 12.5% P. equor 8.3% D. annfieldi and 6.3% F. gigantica.
The equine microfilariae encountered in peripheral blood were *O. reticulata* (32.6%) and *S. equina* (19.6%). Moreover, the blood protozoa noticed were *N. equi* (10.3%) and *B. caballi* (6.5%).

The high rate of infection among equines in Assiut territory may be attributed to different factors of climatic, environmental conditions and hygienic disposal of animal manure, as well as the arthropod vectors which are distributed in areas such as Assiut town, Upper Egypt. Monthly observations of the distribution of equine microfilariae revealed a highest rate of infection during autumn, summer, and spring, while the prevalence of infection was minimum in winter. This is in agreement with that mentioned by SELIM and FOUAD (1964). The present authors suggest that, the age of the animals, breed, sex, the chronicity of the disease and the locality may affect the incidence of infection. The equine microfilariae was studied and it appeared to be non seasonal and these results disagree with that mentioned by MOHAMED (1979) who stated that the highest mean number of microfilariae was at mid night while the lowest mean number of microfilariae was during the period between noon and 4 P.M. Also, the present results disagree with those obtained by BUSA (1955), who reported that the microfilariae tend to reach their maximum in the blood in the evening. The present authors explained this phenomena by the active feeding period of the arthropod vector which is not restricted to certain time. Furthermore, prophylactic measures against the frequency of infection with these parasites as well as the arthropod vectors should be considered by our authorities to prevent the distribution of infection with special references to Arab horses which are considered to be one of the most economic animals in Egypt.
